

DATA ACQUISITION

Circuit Puts Analog Data into Excel

Clayton B. Grantham
Burr-Brown Corp., Tucson, AZ

A few integrated circuits, a simple Excel 5 macro, and a driver are all you need to transform a PC into a virtual voltmeter. The resulting 16-bit voltmeter circuit offers an input range of up to ± 200 V, resolves to 6.1 mV, and has an accuracy of 0.005% after calibration.

The interface circuit (Fig. 1) that connects the 16-bit ADS7807 analog-to-digital converter (ADC) IC to a PC's parallel port is simple. The control software forces nine of the port's signal lines to a high state, which lets the corresponding pins provide power to the circuit through 10- Ω resistors. Using the parallel interface's data lines to power the interface

may not work for all PCs, though. If your PC cannot supply clean 4.75-V to 5.25-V DC power to the circuit, use an external source to supply the 35 mW the circuit needs. (For more information about the parallel port, see the IEEE 1284 standard,¹ which provides a thorough description of signals, controls, and hardware for a PC's parallel interface.)

The 74HCT04 inverter in the interface circuit provides a clean signal to a monostable (10-k Ω resistor and 100-pF capacitor) that produces a 150-ns logic-zero pulse for the ADC's R/C* input. When the R/C* input goes to a logic zero, the ADC starts a conversion. The short pulse ensures that the R/C* input is back at logic one before the ADC's BUSY* (conversion complete) signal

goes to a logic one. The short pulse width also minimizes any digital feedthrough that might occur during a conversion.

Select a Byte

The 16-bit ADC's BYTE input selects the byte that appears at the ADC's outputs. In turn, the 74HCT157 multiplexer selects which nibble (four bits) of each byte to transmit to the parallel port. The macro controls the flow of four nibbles to the PC and reconstructs them into a 16-bit integer.

By itself, the ADS7807 has an input voltage range of ± 10 V. Using an 866-k Ω input resistor, however, extends the range to ± 200 V according to the equation:

$$V_{in(max)} = \pm 10 \text{ V} * (1 + R_{ext}/45.5k)$$

To reduce noise on your signal, place a capacitor between the ADS7807's input and ground to form an RC network with the input resistor.

To acquire voltages, select a cell or a range of cells in a spreadsheet and then execute the macro (Fig. 2, p. 14),

(text continued on p. 16)

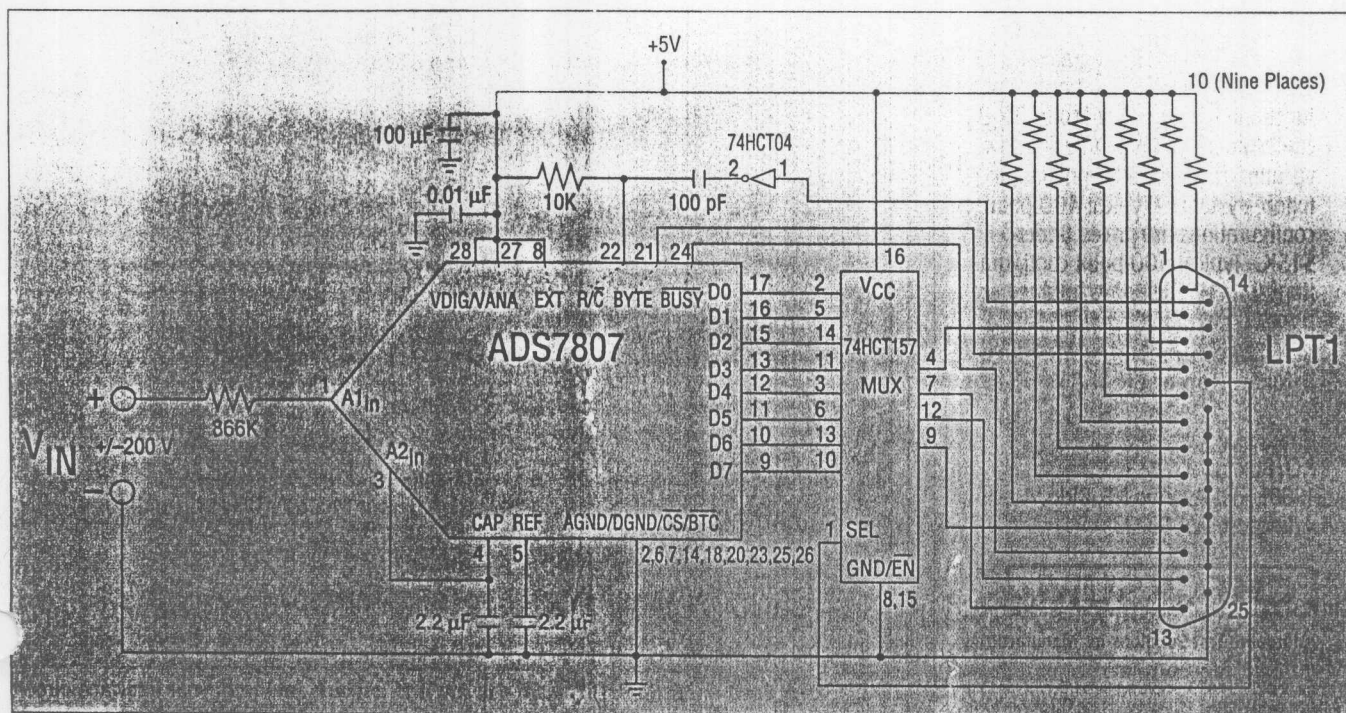

FIGURE 1. The circuit for the ADC interface requires only a few TTL ICs to transfer data to an Excel spreadsheet under software control.

Checksum adds SMT coverage to MDA Test!

HP TestJet technology[®]
means greater test coverage!

Checksum, Inc., America's leader in MDA test, introduces unsurpassed test coverage in the new Model TR-8 Manufacturing Defects Analyzer (MDA). Fault coverage is optimized by combining new higher-bandwidth measurement and guarding capabilities with HP TestJet technology. This award-winning technology finds open pins, even on surface-mount devices.

Power-down testing with the Model TR-8 finds opens, shorts, incorrect and incorrectly installed components on circuit assemblies. The CheckSum Model TR-6 can be integrated to provide complementary power-up functional testing. The Model TR-8 can be combined with CheckSum's vacuum, mechanical or pneumatic fixture systems. Typical 400-point configurations are priced under \$15K. Typical 400-point configurations with HP TestJet technology are priced under \$30K.

Call CheckSum today for more information at (360) 435-5510.

Checksum, Inc.
P.O. Box 3279
19009 61st Avenue NE, Bldg. 4
Arlington, WA 98223

Affordable Test Solutions for Manufacturing

*HP TestJet technology is protected under U.S. patent number 5,254,953. Implementation, service, and support of HP TestJet technology on the CheckSum Model TR-8 is the sole responsibility of CheckSum, Inc.

TEST TIPS & TECHNIQUES

The following macro communicates through the PC's parallel printer port with the dynamic-link-library, CUSER3.DLL.
Parallel port initialization

Declare Sub Out Lib "CUSER3.DLL" (ByVal Addr%, ByVal Byte%)
Declare Function Inp Lib "CUSER3.DLL" (ByVal Addr%) As Integer

Sub ADSInput()

Dim Datum As Integer

Temporary data element

'Hexadecimal Port Addresses

DataPortAddr = &h378

StatusPortAddr = &h379

ControlPortAddr = &h37a

If TypeName(Selection) <> "Range" Then Exit Sub

Out ControlPortAddr, &h4 Initialize control port

Out DataPortAddr, &hff Power up ADS7807

For i = 1 To Selection.Count

Out ControlPortAddr, &h6 Start Conversion

For j = 1 To 2 Wait for notBusy signal

Next j Not needed for slow PCs

If (Inp(StatusPortAddr) And &h80) Then

Selection.Item(1).Value = "HDErr: Hardware error"

Exit Sub

End If

'Input low byte, high nibble. Isolate & shift nibble up.

Datum = ((Inp(StatusPortAddr) And &h78) * &h2)

Out ControlPortAddr, &hc Select low byte, high nibble

'Input low byte, low nibble. Add in nibble and place in cell

Datum = Datum + (Inp(StatusPortAddr) And &h78) / &h8

Selection.Item(i).Value = Datum

Out ControlPortAddr, &h0 Select high byte, high nibble

'Input high byte, high nibble. Isolate nibble

Datum = (Inp(StatusPortAddr) And &h78)

If (Datum And &h40) Then

Test MSB of nibble for negative value

Scale negative values & shift nibble to top of word

Datum = -32768 + (Datum And &h38) * &h200

Else Datum = Datum * &h200 Shift nibble to top of word

End If

Out ControlPortAddr, &h8 Select high byte, low nibble

'Input high byte, low nibble. Isolate & shift nibble up & add to word

Datum = Datum + ((Inp(StatusPortAddr) And &h78) * &h20)

'Convert result to signed floating point

Selection.Item(i).Value = (Datum + Selection.Item(i).Value) / 32768

'Scale result with offset and gain calcfactors for +/- 200V input

Selection.Item(i).Value = (Selection.Item(i).Value - 1.712) * 19.704

Out ControlPortAddr, &h4

Reset for another conversion

Next i

End Sub

FIGURE 2. Load the Excel Basic macro and run it to acquire data from your interface circuit. Be sure the hexadecimal port addresses match the addresses on the port you're using.

```

Sub SoftCal()
Set B1 = Worksheets("MyWorksheet").Range("B1")
Set B2 = Worksheets("MyWorksheet").Range("B2")
Set B3 = Worksheets("MyWorksheet").Range("B3")
Set B4 = Worksheets("MyWorksheet").Range("B4")
Message = "Connect CAL source to Input; Enter CAL Value"
FirstCalValue = Val(InputBox(Message))
B1.Select
ADSinut
Message = "Change CAL source; Enter CAL Value"
SecondCalValue = Val(InputBox(Message))
B2.Select
ADSinut
B3.Value = (FirstCalValue - SecondCalValue) / (B1.Value - B2.Value)
* Gain coefficient.
B4.Value = FirstCalValue / B3.Value - B1.Value
Offset coefficient.
End Sub

```

FIGURE 3. If you don't want to use hardware trimmers, use this short macro to obtain gain and offset values.

which contiguously fills each cell with a measurement. The Excel macro uses a dynamic link library routine, CUSER3.DLL, to communicate with the ADC through the PC's parallel port. (T&MW provides the DLL file for free; see "Notes," this page.) Be sure to transfer the CUSER3.DLL into your main Excel directory so the macro can locate it.

Control Your PC's Ports

To keep Excel Basic—the Basic-like language built into Excel—independent of hardware, Microsoft excluded commands that control specific I/O ports. The CUSER3.DLL circumvents this limitation and lets you transfer bytes to output ports and retrieve bytes from input ports.

Typically, a PC's parallel port resides at h0378 (data), h0379 (status), and h037A (control). Check your PC's manual to be sure you have the proper addresses for the port you want to use. If necessary, change the three address definitions at the start of the macro.

When you run the macro, it initializes the control byte and starts the ADC. After a delay of at least 25 μ s, the macro checks the ADC's BUSY signal. At the end of a conversion, the macro inputs the ADC's data. For example, if you select 15 cells, the macro acquires 15 readings, one after the other. The timing between conversions depends on your PC's timing and the timing overhead of Excel. My 33-MHz 486-based PC took 23 ms per conversion, and the Nyquist bandwidth was 22 Hz.

Calculate Offset and Gain Errors

The basic circuit doesn't compensate for gain and offset errors. You can use nominal ADS7807 offset and gain errors (without external trimming) to scale the results obtained with the macro. Use the code shown in Fig. 3 with the ADSinut() macro to provide gain and offset coefficients, if you need them. To achieve the highest accuracy, add external trimmer resistors to the circuit.² T&MW
